Non-viral methods present certain advantages over viral methods, with simple large scale production and low host immunogenicity being just two. Previously, low levels of transfection and expression of the gene held non-viral methods at a disadvantage; however, recent advances in vector technology have yielded molecules and techniques with transfection efficiencies similar to those of viruses .

*Gene Therapy Non-Viral Vectors Explained*

16.5.1 Plasmid DNA carrier vehicles: non-viral vectors. Non-viral vectors are DNA plasmids that can be delivered to the target cells as naked DNA or in association with different compounds such as liposomes, gelatin or polyamine nanospheres. Despite their safety, ability to avoid the immune response and ability to carry large amounts of DNA insert, they possess a low myocardial delivery, poor transduction efficiency and transient expression.

Non-viral vectors are currently being evaluated for long-term expression of the therapeutic genetic material. The most actively researched non-viral vectors include chemical disruption Chemical disruption vector a type of vector that is typically designed to target specific cells and increase the delivery of genetic material to cytosol or nucleus

Non-viral vector: Liposome, naked DNA, nucleofection, and transposons are some of the non-viral vector-mediated methods used for gene therapy. Why the non-viral vector will be one of the best opportunities for the gene transfer? The non-viral vectors are non-toxic, non-immunogenic, and tissue-specific. Also, it is easy to design and apply them.

Non-viral vectors : 1. Highly efficient in transferring desired genes. Less or fairly efficient in transferring desired genes. 2. Viral vectors pose some health risk to the recipient. Patient. Non-viral vectors are usually safer to use, and they do not pose any health risk to the recipient patient. 3. Viral vectors are used for in vivo gene therapy to

Cationic lipids, being important and potential non-viral gene vectors, have more advantages, such as biodegradability, low cytotoxicity, structure variety, and easy production, as compared to other systems. Despite their low immunogenicity, non-toxicity, and easy synthesis, cationic lipids have low transfection efficiency.

Non-Viral Vectors. Non-viral vectors can be loosely grouped as plasmid DNA, liposome-DNA complexes (lipoplexes), and polymer-DNA complexes (polyplexes) (1). Oligonucleotides and their analogues, either alone or in complexes, are also an example of non-viral vector-mediated gene transfer. A substantial number of the human cardiovascular gene therapy protocols are based on plasmid-mediated gene transfer (2).

Gene delivery systems include viral vectors and non-viral vectors. Viral vectors are the most effective, but their application is limited by their immunogenicity, oncogenicity and the small size of the DNA they can transport. Non-viral vectors are safer, of low cost, more reproducible and do not present DNA size limit.
